

Local supermarket system

I was tasked to build a management system for a small supermarket including products, stock, suppliers, sales, and reports. Providing useful information in Decision making.

I made a diagram using Miro to display all the parts of the system.

Category, product, Stock item and supplier are the objects of the system.

I used Linear Search for the products and entity framework for the system. Using visual studio's System.data.entity and sql.

I attempted to use Microsoft's Entity.data.framework but it failed on multiple occurrences.

I implemented Crud operations and attempted to implement linear search for the product search. I also created database sets and entity relationships.

The project overall was a Failure; the planning was rushed and inconsistent. There was no proper testing. The deadline would have not been met at all. This being a solo project meant having to design and implement the entire system causing errors with the entity relationships. The unawareness of many problems early in the planning resulted in large

problems further ahead of the project such as the frontend. Struggling to find out how to solve these problems and lack of confidence in being able to improve the system resulted in failure.
